

On Computable Coordinate Systems: Definition, Operations, and Computer Code Implementation

by **Guojun Pan**

(DMS Software CO., Ltd.)

Abstract: *Matrix operations are often used in coordinate system transformations, while tensor operations are utilized in more general situations. The former belongs to the category of "raw" mathematical objects, which are not designed for coordinate system transformations and have problems with redundancy and convenience in the calculation process. The latter is difficult to master and challenging to use numerically. This paper introduces a specialized structure object for coordinate system transformation as a substitute for matrix and tensor operations.*

1. Introduction

Coordinate systems have always been the most abstract and difficult mathematical and physical objects, and the development of tensor operations has made them even more abstract, requiring years of training to barely master. Therefore, it is necessary to explore a simplified method to address the challenges of coordinate system operations. Although matrix operations are commonly used in coordinate system transformations, they are not designed for this purpose and are too mathematical and vague in meaning. Tensors, on the other hand, are too abstract and difficult to master, and it is difficult for computers to quantify them.

A concept specifically designed for coordinate system transformation is needed.

2. Design

A mathematical object named "coord" is designed based on group theory to perform arithmetic operations. The definition of the coordinate system structure is as follows: a three-dimensional coordinate system consists of an origin, three directional axes, and three scaling components, representing translation, rotation, and scaling transformations.

a) Definition of coordinate system structure

The coordinate system in three-dimensional space consists of an origin plus three direction axes and three scaling components, corresponding to the three transformations of **translation, rotation, and scaling**, respectively (C++ version):

```
struct coord
{
    vec3 ux, uy, uz;    // Three unit basis vectors
    vec3 s;             // Scaling
    vec3 o;             // Origin Position
}
```

Construct a coordinate system object (C++ version).

By three axes

```
coord C(vec3 ux, vec3 uy, vec3 uz)
coord C(vec3 ux, vec3 uy);
```

By Euler angles

```
coord C(float angle, vec3 axis);
coord C(float pitch, float yaw, float roll);
```

(Origin and scaling can be directly set)

b) Multiplication: Define a vector in a certain coordinate system

Figure 1: Define a vector in a coordinate system, with each component defined on its respective coordinate axis.

Use multiplication to transform a vector from the local coordinate system to the parent coordinate system and to merge coordinate systems.

For example: V_0 is defined in the world coordinate system C_0 , and V_1 is defined in the C_1 coordinate system.

$$V_0 = V_1 * C_1$$

Figure 2: Vector V_1 is defined in coordinate system C_1 , with C_1 being the parent coordinate system of C_0 .

C1, C2, and C3 are local coordinate systems in three scene nodes, and the parent-child direction is:

$$\mathbf{V}_0 = \mathbf{V}_3 * \mathbf{C}_3 * \mathbf{C}_2 * \mathbf{C}_1 = \mathbf{V}_3 * (\mathbf{C}_3 * \mathbf{C}_2 * \mathbf{C}_1)$$

Multiplication after swapping with vectors:

$$\mathbf{V} * \mathbf{C} \neq \mathbf{C} * \mathbf{V}$$

Define the coordinate system and multiply the vector:

$$\mathbf{C} * \mathbf{V} = \text{Lerp}(\text{ZERO}, \mathbf{C}, \mathbf{V})$$

where Lerp is a linear interpolation function.

c) Division: Measure a vector using a certain coordinate system

Figure 3: Measuring a vector V using a coordinate system, with each component value being the projection of V onto each coordinate axis.

Use division to project from the parent coordinate system to the local coordinate system. For example:

V0 is defined in the world coordinate system C0, and V1 is defined in the C1 coordinate system:

$$\mathbf{V}_1 = \mathbf{V}_0 / \mathbf{C}_1, \mathbf{V}_0 = \mathbf{V}_1 * \mathbf{C}_1$$

V2 is defined in the C2 coordinate system:

$$\mathbf{V}_2 = \mathbf{V}_0 / C_2 = \mathbf{V}_1 * C_1 / C_2$$

C1, C2, and C3 are local coordinate systems in three scene nodes, and the parent-child direction is:

$$\mathbf{V}_3 = \mathbf{V}_0 / C_1 / C_2 / C_3 = \mathbf{V}_0 / (C_3 * C_2 * C_1)$$

d) Usual Application Scenarios

1. For example, a vector \mathbf{V}_w in world space is converted to the local coordinate system C:

$$\mathbf{V}_L = \mathbf{V}_w / C$$

Conversely: $\mathbf{V}_w = \mathbf{V}_L * C$

2. Conversion between world coordinate system and local coordinate system

$$C = C_3 * C_2 * C_1$$

$$\mathbf{V}_w = \mathbf{V}_L * C, \quad \mathbf{V}_L = \mathbf{V}_w / C$$

3. Multiple node hierarchy use

Vector \mathbf{V}_5 is defined in the coordinate system of node 5, in the parent node at the level of node 2:

$$\mathbf{V}_2 = \mathbf{V}_5 * C_5 * C_4 * C_3$$

Each coordinate system is a local coordinate system

$$\text{Conversely: } \mathbf{V}_3 = \mathbf{V}_2 / C_3 / C_4 / C_5$$

4. Conversion between parallel coordinate systems

$C0$ // $C0$ under the parent coordinate system

$C1, C2$ // Two flat sub-coordinate systems

Convert a vector from $C1$ to $C2$ coordinate systems

$$\mathbf{V2} = \mathbf{V1} * C1 / C2$$

e) Addition and subtraction

When calculating the difference between two vectors:

$$d\mathbf{V} = \mathbf{V1} - \mathbf{V2}$$

$$\text{Let: } \mathbf{V1} = \mathbf{V} * C1, \mathbf{V2} = \mathbf{V} * C2$$

$$d\mathbf{V} = \mathbf{V} * (C1 - C2)$$

Here defines an addition and subtraction operation for basic addition and subtraction of vectors:

$$\mathbf{V1} + \mathbf{V2} = \mathbf{V} * (C1 + C2)$$

$$\mathbf{V1} - \mathbf{V2} = \mathbf{V} * (C1 - C2)$$

To facilitate our operations, we establish a principle: for objects of different types, the operation structure remains the same as the object on the left side of the operator.

For example:

$$\mathbf{V}(\text{vector}) = \mathbf{Vc}(\text{vector}) * C(\text{coordinate})$$

3. Advanced Application Scenarios

a) Coordinate System Differentiation

Differentiation of the coordinate system in space corresponds to three common forms:

1) Gradient: $\nabla f = \mathbf{U} * df * C_{uvw} / d\mathbf{xyz}$

Here, \mathbf{U} represents the basis vector \mathbf{U} in the local coordinate system, df represents the amount of change, C_{uvw} represents the local coordinate system, and $d\mathbf{xyz}$ represents the vector element defined in the world coordinate system.

2) Divergence: $\nabla \cdot \mathbf{F} = d\mathbf{F} / d\mathbf{xyz} \cdot \mathbf{I}_c$

Here, \mathbf{I}_c is the default world coordinate system.

The dot product and cross product operations can be appropriately defined between vectors and coordinate systems.

3) Curl: $\nabla \times \mathbf{F} = d\mathbf{F} / d\mathbf{xyz} \times \mathbf{I}_c$

The formula for vector division is :

$$V1 / V2 = (V * C1) / (V * C2) = C1 / C2$$

where V represents the vector and $C1, C2$ represent the coordinate systems.

In order to facilitate numerical calculations, we set a sufficiently small scaling factor ϵ for the global coordinate system, where we can approximately perform linear operations and ignore higher-order terms.

On this scale, we can use the unit one to replace the differential quotient

factor of derivatives, thereby directly using differentials instead of derivatives, achieving the goal of simplifying expressions.

Therefore, the gradient expression mentioned above can be written as:

$$G = C2 / C1 - I$$

Here $C1$ and $C2$ are two adjacent coordinate systems that are a unit length apart. I is the identity coordinate system.

Note: In the following text, we will use this method to calculate differential geometry subjects.

b) Applications in the Field of Differential Geometry

1) Movement of Vectors

Assuming a flat space, a natural coordinate system is defined in which a vector V can move freely without changing. When observed under a curved space coordinate system, V varies at different points, indicating that the coordinate system is position-dependent. Let (1) and (2) be two adjacent points with vectors $V1$ and $V2$ at each point, corresponding to coordinate systems $C1$ and $C2$. Then, we have:

$$V = V1 * C1 = V2 * C2 \Rightarrow$$

$$V2 = V1 * C1 / C2,$$

$$\text{Let: } R12 = C1 / C2 \Rightarrow$$

$$V2 = V1 * R12$$

Figure 4: Defining two coordinate systems on a surface space, where vector V_1 is translated from one point to another, resulting in V_2 .

An arbitrary differential vector can be defined as:

$$d\mathbf{w} = d\mathbf{u} * R_w$$

So to move in any direction of a differential vector:

$$\mathbf{V}_2 = \mathbf{V}_1 * R_w = \mathbf{V}_1 * R_u \wedge (\mathbf{u} \cdot d\mathbf{w})$$

$$\text{where: } R_u = R_{12} = C_1 / C_2, \quad \|\mathbf{u}\| = 1$$

This quotient represents the variation of two coordinate system objects C_1 , C_2 in the direction of the unit differential vector dU .

2) Exponential Operation of Coordinate Systems

When a coordinate system is translated along the arc of a differential space, it often involves rotation. To calculate the derivative of rotation with respect to translation, as rotation computations involve division (e.g. $R_{12} = C_1/C_2$), the derivative operation can be performed using exponential notation.

A coordinate system can be represented in exponential form: $C = e^{\wedge}(V)$.

Considering the coordinate systems at the two ends of a differential space arc, u_1 and u_2 , we have:

$$C_1 = e^{\wedge}(\mathbf{n}_1), \quad C_2 = e^{\wedge}(\mathbf{n}_2)$$

$$R_{21} = C_2 / C_1 = e^{\wedge}(\mathbf{n}_2 - \mathbf{n}_1)$$

$$\text{let } d\mathbf{n} = \mathbf{n}_2 - \mathbf{n}_1, \quad d\mathbf{u} = \mathbf{u}_2 - \mathbf{u}_1$$

$$\text{Derivative } C' = e^{\wedge}(d\mathbf{n} / d\mathbf{u})$$

$$R_{21} = C' \wedge d\mathbf{u},$$

$$\text{where } ||d\mathbf{u}|| = 1, R_{21} = C'$$

To perform translation of a coordinate system on a surface, the formula can be used:

$$C_2 = C_1 * R_{21}^{\wedge} (\mathbf{u}_2 - \mathbf{u}_1)$$

3) Curvature Calculation

Figure 5: In a small element of the surface space, when a vector is translated along two perpendicular directions, the final result may differ depending on the path taken.

The coordinate system object is capable of converting vectors from the natural coordinate system to the curved coordinate system. The curvature can be calculated by comparing the difference in vector translation along the $u \rightarrow v$ and $v \rightarrow u$ paths, using G_u and G_v . G_u and G_v represent the gradient of rotational changes along the u and v vectors. By utilizing the coordinate system, spatial curvature can be calculated, and the coordinate equivalent representation of the Riemann curvature tensor can be given in the u, v

coordinate system as:

$$R_{uv} = G_u * G_v - G_v * G_u - G[u,v]$$

$$\text{Where } G_u = C_u / C_0 - I$$

$$G_v = C_v / C_0 - I$$

I is the identity coordinate system.

C_0 corresponds to the initial coordinate system.

Connection vector: $[u, v]$ (Lie bracket operation)

Let $W = [u, v]$, W_u and W_v are the two components of W . Using the coordinate system and vector exponential multiplication mentioned earlier, we can calculate the changes in the gradient coordinate system along them:

$$G[u,v] = G_u * W_u + G_v * W_v$$

4. Combination with Lie groups, Lie algebras

The rotation matrix R belongs to a Lie group, and the multiplication operation of our coordinate system is equivalent to the rotation matrix. Therefore, our coordinate system C is also a Lie group element, with multiplication as its operation and ONE as its identity element:

$$C \in \{ONE, (*)\}$$

The vector fork multiplies the corresponding coordinate system

$$v_1 \times v_2 = v * C_1 \times (v * C_2)$$

Let $v = \text{vec3}(\text{ONE})$, then $C * v = C$, so the above equation can be written as:

$$v_1 \times v_2 = v * (C_1 \times C_2)$$

We define a coordinate system cross product operation expressed in Lie algebra brackets:

$$[C1, C2] = C1 * C2 - C2 * C1;$$

5. Conclusion

The coordinate system object can simplify the linear operation in local space, and some operations can be appropriately designed when calculating vector movement and rotation operations, and a unified form can be formed according to the rules of group theory. It can be applied to situations that require a lot of linear operations, such as constraint calculations. Vectors, matrices, and tensors are combined through coordinate system objects, and Lie groups and Lie algebraic objects are unified into a ring, forming a unified and coherent form.
